Globalisation and Mental Well-being

Abstract

Interactions with business partners in distant countries necessitate working across time zones and hence outside traditional working hours, which can take a toll on the mental well-being of workers. This effect is likely to be stronger for (i) women who juggle professional and family obligations, and (ii) workers in occupations requiring contacts with others. These hypotheses are investigated using matched employer-employee data from Denmark merged with information on workers' use of prescription antidepressants (AD) and firms' import and export transactions. The analysis exploits variation within job spells and controls for both unobservable firm-year heterogeneity and for the average differential in annual AD use among men and women. The results indicate that a decline in the business hour overlap between a Danish firm and its foreign trading partners leads to an increased AD use among women relative to men. This effect is economically meaningful, largest for college educated workers under 45 and more pronounced for single mothers. In addition to the gender effect, workers in occupations requiring establishing relationships with others are more strongly affected than those in other occupations.

1 Introduction

Recent decades have seen rapid growth in international trade and foreign direct investment, as firms have created supply chains spanning the globe in order to optimise production costs and reach customers in distant parts of the world. Running these complex production and distribution networks requires interactions with customers and suppliers located in different time zones, and thus may necessitate working outside of standard business hours. This in turn may be difficult to reconcile with family obligations. Working across time zones may thus disrupt the work-life balance and take a toll on the mental well-being of workers.¹

This study aims to shed light on the consequences of working across time zones for the mental well-being of workers, proxied by their use of prescription anti-depression medications. We use matched employer-employee data from Denmark for 2008-2017, encompassing the universe of Danish firms in the private sector, combined with detailed customs data on exports and imports. Importantly, we observe comprehensive information covering every individual worker's prescription drug purchases, disaggregated by drug type. Our outcome of interest is an indicator variable capturing whether a worker has purchased prescription antidepressants in a given year. We follow Bøler et al. (2018) and proxy working across time zones by using business hour overlap between Denmark and its export and import markets, weighted by the number of products sold or purchased in a given country.²

Our identification strategy rests on three pillars. First, we condition on job-spell fixed effects, i.e., we exploit time variation in the firm's business hour overlap with its trading partners within a given worker-firm relationship. This allows us to account for idiosyncratic and time-invariant factors that affect individuals' health, such as pre-natal and early-life environment and genetic differences (e.g. Black et al. (2007)).

Second, we conjecture that working across time zones is particularly difficult for women

¹For instance, an employee of a global company reported that “[d]epending on what country he is working with, he has to adjust his time for fathering. When he was working with Malaysia he lost time with his children in the mornings, because he had to be online with their [Malaysian] time. When he is working with Austria the time with the kids in the afternoon and evening has to be adjusted to the working hours in Austria.” (Kvande, 2009, pp. 68-69)

²Danish health care is free and universal, with every individual having access to health care regardless of income and employment status. This makes Denmark a better setting for our study than, for instance, the U.S., where workers' access to health care is correlated with income and employment status (e.g. Currie and Madrian (1999)) and enables us to separate the direct effect of work characteristics on well-being from an indirect effect operating through access to health care. See section 2 for a more detailed discussion of the healthcare system in Denmark.

because of the need to juggle work and family obligations and even more so for young women (i.e., those under 45 years of age) who are likely to have young children.³ We focus on the gap in antidepressant usage between women and men working for the same firm in a given year, which allows us to control for unobservable firm-year-specific heterogeneity that may, e.g., drive firms' internationalization, corporate culture, or impact the average level of stress among the workforce. To account for differential propensity to use antidepressants among the genders over time, we control for an interaction of a female indicator with year dummies. We also control for education, experience, experience squared, having children and 2-digit occupational fixed effects.

Third, in addition to focusing on differences between genders, we exploit differences between occupations. In particular, we conjecture that occupations necessitating greater interactions with others and requiring establishing and maintaining personal relationships would be to a larger extent affected by a lower business hours overlap.

To summarize, our analysis holds the worker-firm match fixed, controls for unobservable firm-year heterogeneity, and asks how a change in the firms' business hour overlap with its foreign buyers and suppliers translates into a differential antidepressant use among (i) its female and male workers, (ii) workers in occupations that require greater interactions with others, establishing and maintaining personal relationships versus occupations where these factors play a lesser role.

Our results can be summarized as follows. First, we find a positive and statistically significant relationship between working across time zones and the gender gap in antidepressant usage. In other words, a lower business hour overlap is associated with a higher incidence of antidepressant usage among women relative to men. This relationship is present among college-educated workers, but not in the general population of workers. This is intuitive, as college-educated workers are more likely to hold jobs in management, sales, marketing, customer support, or other occupations that necessitate interactions with foreign business partners. This relationship is only found among younger (under 45), which is in line with younger workers being more likely to have small children and, therefore, more family obligations. Moreover, the relationship between working across time zones and antidepressant use is particularly strong among young workers with a college education.

³As shown by Thielemans et al. (2019), women tend to perform a higher share of household work than men do. This is also in line with the findings of Bøler et al. (2018) who show that working across time zones is associated with a higher gender wage gap in Norway.

The estimated magnitude is economically meaningful. A decline in business overlap by 5 hours, equivalent to moving all trade from Germany to the eastern part of Canada, is associated with a 1.7% point increase in the likelihood of antidepressant use by women relative to men among college-educated workers under 45. This implies increasing the prevalence of antidepressant use by 57%, which in this subpopulation is equal to 3%. Our results are robust to controlling for firms' business exposure to less gender-equal countries, thus eliminating the possibility that gender biases and stereotypes among business partners make the working lives of female employees more stressful. They are also robust to dropping the period of the Global Financial Crisis (2008-9) to eliminate the possibility of economic downturn affecting our results.

Second, our hypothesis that the need to work outside of standard business hours is especially taxing for employees juggling work and family obligations finds support in the analysis allowing for a differential effects for single mothers. This analysis shows that the impact of working across time zones on antidepressant usage is more 3-4 times larger for single mothers than for women in general, which suggests that the pressures of maintaining work-life balance are likely to be one of the main factors driving our results. Again this effect is more than twice as large for college educated single mothers than for mothers without college education.

Third, we document a similar relationship for business hour overlap with respect to foreign subsidiaries of Danish companies. Again, an increase in the need to work across time zones necessitated by the need to communicate with the firm's foreign subsidiaries is associated with a greater gender gap in antidepressant use. This relationship holds for younger workers with a college education and is *in addition* to the effect driven by the composition of foreign trade.

Fourth, following Goldin (2014), focus on five occupational characteristics (available from O*NET) that limit the temporal flexibility of workers, as they are linked to working particular hours and long hours. We find that a lower business hours overlap is associated with a greater antidepressant usage among workers in these occupations (relative to those employed in other occupations). This effect holds *in addition* to our finding on women being affected more than their male colleagues. When we zoom in on individual job characteristics, we find that the results are driven by occupations (i) requiring establishing and maintaining interpersonal relationships, (ii) requiring contact with others, (iii) with fewer substitutes for a given worker. These effects are economically meaningful. For instance, workers in the top quarter of occupations where

contact with others is required see a 0.9 percentage point increase in antidepressant use when the business hour overlap declines from 8 to 3 hours.

It is worth reiterating that our results are not driven by self-selection of workers into particular firms or by self-selection of firms with a healthier workforce into greater internationalization, as we hold the work-firm match fixed and control for firm-year fixed effects. Moreover, the inclusion of female-year fixed effects means that our findings cannot be attributed to the changing incidence of antidepressant usage between men and women over time.

Taken together, our results are consistent with the need to work across time zones, and thus outside of standard business hours, taking a toll on mental well-being of workers. The contribution of our study lies in documenting this effect as well as pointing out a new channel through which globalisation differentially affects men and women as well as workers in particular occupational groups. Our study also contributes to improving understanding of factors leading to or exacerbating depression. This is interesting in its own right, given that depression alone accounts for 4.3% of the global burden of disease and is among the largest single causes of disability worldwide (accounting for 11% of all years lived with disability globally), particularly for women. This has not only impact on the affected individuals and their families, but has also large economic consequences in terms of lost days of work and output losses globally (WHO (2021)).

Our paper is related to several strands of the existing literature. The first one encompasses studies on the gender impact of globalisation, most of which focus on the gender wage gap (GWG). Juhn et al. (2014) argue that trade liberalization induces prospective exporters to adopt new technology that is more modern and requires less physical strength from workers. This improves women's labor market outcomes in the blue-collar tasks, while leaving them unchanged in the white-collar tasks. They find that the introduction of NAFTA was associated with entry of new firms and adoption of more modern technology, at the same time as firms hired relatively more blue-collar females and increased their share of the wage bill. Bøler et al. (2018) argue that there is a systematic difference in the GWG between exporting firms and non-exporters, as the latter requires working particular hours to communicate with partners in different time zones and may therefore disproportionately reward employees' flexibility. If women are less flexible, or perceived as such, exporters will exhibit a higher GWG than non-exporters. This

hypothesis is confirmed by an analysis of matched employer-employee data from Norway. Their results suggest a firm’s entry into exporting increases the GWG by about 3 percentage points for college-educated workers. A lower overlap in business hours between the Norwegian exporter and its foreign markets and a greater need for interactions with foreign buyers are associated with a higher GWG. The contribution of our study lies in pointing out another channel through which globalisation may lead to differential outcomes for men and women, namely mental well-being.⁴

Our paper also contributes to the nascent literature on work-induced health outcomes. Hummels et al. (2023) employ the same Danish data to study the effect of rising workload on health. Using both within-job-spell regression analysis and cohort event studies, they show that large increases in firm sales lead workers to log longer hours and experience higher probabilities of stress, depression, heart disease, and strokes, with more pronounced effects for high-risk groups such as older workers, job-strained workers, and those with long initial work hours. We differ from their paper in that we focus on stress caused by working across time zones necessitated by firms’ internationalization rather than demand surges. In another related study, Belloni et al. (2022) use survey-based assessment of depressive symptoms among UK workers to investigate how EU-wide occupation-level changes in working conditions affect mental health. They consider an index of working time quality which captures working long or atypical hours (i.e., working more than 48 hours a week or 10 hours a day, night or weekend work, shift work), frequently changing work schedule or work schedule changing at a short notice and the lack of control over work schedule. They document that a deterioration in working time quality is associated with worse mental well-being. A one-standard deviation decrease in jobs’ working time quality increases depression score by 0.97 points. Our study improves over their analysis by using an objective measure of mental well-being (namely, use of prescription medication) and by analysing changes to working conditions in the workplace place of a given individual (rather than in the EU conditions specific to a given occupation).

Our study also speaks to the broader literature on the impact of globalization on health outcomes. This literature has predominantly focused on the negative effects of import competition, such as greater incidence suicides and drug overdoses (Pierce and Schott, 2020), more job-related

⁴Another strand of the literature documents the positive effects of foreign ownership on female employment thanks to multinationals transplanting their meritocratic culture and flexible working arrangements to foreign affiliates (Kodama et al. (2018), Tang and Zhang (2021), Choi and Greaney (2022)). Our study contributes to this body of research by demonstrating that by working across time zones necessitated by the presence of foreign affiliates may increase the gender gap in mental well-being.

injuries (McManus and Schaur, 2016), and deterioration in physical and mental health of workers (Adda and Fawaz (2020), Colantone et al. (2019)). However, this literature has also documented a decline in workplace accident rates in the aftermath of foreign acquisitions (Javorcik et al., 2023). Our contribution lies in drawing attention to the taxing effects of working across time zones which is necessitated by globalization.

Finally, our paper is also related to the literature documenting how time zone differential affects the organization of knowledge within multinational firms (Gumpert (2018)), collaboration between inventors (Bircan et al. (2022)) and the gender wage gap (Bøler et al. (2018)). We contribute to this literature by pointing out the negative impact of working across time zones on workers’ mental well-being.

The rest of the paper is structured as follows. The next section describes the data sources and the definitions of the main variables. Section 3 discusses the estimating equation. Section 4 presents the empirical results on the gender gap in mental well-being. Section 5 focuses on robustness checks. Section 6 exploits differences in occupational characteristics. Section 7 presents the conclusions.

2 Data and Setting

In this section, we first discuss the main features of the Danish healthcare system, with a focus on mental well-being. Secondly, we describe the datasets used and the construction of the regression sample.

2.1 Healthcare in Denmark

In Denmark, all citizens have free and equal access to a high-quality health care system, independent of employment status. Around 84% of all health care expenditures were publicly financed in 2015 while the remaining 16% were financed (mostly) through patient co-payments (The Ministry of Health (2017)).⁵

To get access to health care services, each resident has an assigned general practitioner (GP). Around 5.1 million Danes met their GP (physician) at least once in 2022, 2.4 million men and 2.7 million women (Statistics Denmark (2024)). Visiting the GP is free of charge, and she acts

⁵For a more in-depth overview of the health care system in Denmark see (The Ministry of Health (2017)).

as a gatekeeper between the primary level and specialized healthcare services. GPs can refer individuals further to see a specialist, however, the vast majority of cases are handled without further examination or specialized treatment (The Ministry of Health (2017)).

It is estimated that in any given year, around 20% of the Danish population experiences a problem with their mental health (The Ministry of Health (2017)). As gatekeepers, managing mental well-being is therefore a core task of Danish GPs, and it is estimated that around 25% of all contacts are related to mental well-being (National Board of Health (2010)). GPs can prescribe antidepressive medications to patients and other treatment alternatives. The cost of prescription drugs is subsidized, and the subsidy depends on the individual's prior consumption of medicine within a period of a year. There is an automatic yearly cap on co-payment that is adjusted each year (as an example, in 2023 the maximum co-payment was DKK 4435 or 643 US dollars).

2.2 Data

We draw information from a number of administrative registers maintained by Statistics Denmark and construct a comprehensive matched worker-firm dataset for the period 2008-2017 for the universe of firms in the private sector in Denmark. The data includes information on individuals (e.g., wages, occupation, health outcomes) and firms (sales, foreign ownership, exports, imports etc.).

The sources of the individual level data are: a) the population register (BEF), b) the integrated database for labor market research (IDA) which holds information about, e.g., labor market status, occupation (four digit ISCO codes) and demographics, c) the family and household register (FAM) where individuals are linked through family ties, and d) the education register (UDDA) from where we draw information about highest completed educational degree. We define measures for health outcomes using the prescription drugs register (LMDB), which includes detailed information on the purchases of prescription drugs for all individuals by drug type (ATC codes). The register is comprehensive and includes all purchases of prescription drugs. This allows us to define our measure for mental health: a dummy variable indicating if the individual has purchased antidepressants in a given year.⁶ Individuals are in all registers identified by the

⁶Antidepressants are identified by the ATC code N06A, more information about the ATC system can be found at the WHO website: https://www.whooc.no/atc_ddd_index/

same personal ID code, which allows us to straightforwardly merge the individual-level data.

The firm-level data come from: a) the firm statistics register (FIRM) which holds information about sales, employment and industry codes, b) the account statistics register (FIRE) from where we obtain a measure of the capital stock of all firms, c) the foreign trade statistics register (UH), where all import and export transactions are registered by detailed product codes (6 digit HS) and origin or destination country, and d), outward foreign affiliate statistics (FATO), which has information about employment, sales, and host country for all foreign subsidiaries of Danish firms. The FATO register is only available for 2010-2017. The firms are in all registers identified by the same firm ID code, and we obtain consistent links between individuals and firms from the FIDA database.

As we are interested in the link between globalisation and mental well-being, we restrict the sample to workers aged 20-60. The final regression sample includes Danish manufacturing firms with more than 10 employees that both import and export.⁷ The final dataset includes just under 2 million worker-year observations from circa 3,400 unique firms. The impact of our sample conditions on the coverage rate of our sample can be seen in Table A1 in the appendix. The sample covers 81% of total Danish manufacturing employment and 98% of Danish manufacturing exports. Simple descriptive statistics at the worker level are shown in Table 1 by gender and education status. For example, women are more likely to use antidepressants: 4.3 percent of college educated women use antidepressants, while the corresponding number for college educated men is 3.0 percent. For workers without a college education, 6.5 percent of women and 4.3 percent of men use antidepressants. As illustrated in Figure A1 in the appendix, the antidepressant use has remained quite stable for each group during the period under study. Appendix A.2 show that there is a lot of within-firm across-time variation in both *bho* and antidepressant usage.

2.3 Business hour overlap (*bho*)

Following Bøler et al. (2018), we define the business hour overlap (*bho*) between a Danish firm and a partner country d as the number of working hours (9:00-17:00) that overlap in Denmark

⁷This condition has been implemented such that if a firm in a single year has fewer than 10 employees, but more than 10 in the year before and the year after, it is kept in the sample for that year.

Table 1: Means for workers in 2008-2017

	Men		Women	
	College	No college	College	No college
ln wage	5.951	5.554	5.800	5.438
Age	42.178	42.965	40.492	43.881
Experience	18.188	22.901	16.218	21.282
Children	1.205	0.900	1.197	0.990
Goldin (2014) O*NET measure	0.530	-0.256	0.583	-0.147
Firm's trade bho	5.570	6.152	5.596	5.888
Parents	58.96%	43.55%	61.17%	49.61%
Single parents	1.61%	1.87%	7.14%	8.05%
Antidepressant users	3.01%	4.29%	4.30%	6.53%
Any AD use in 2008-2017	6.69%	10.15%	9.47%	14.59%
Observations	356,405	1,005,479	220,488	404,694

The sample includes workers aged 20-60, in international manufacturing firms, with more than 10 employees. The years included are 2008-2017. Parental status is defined as having a child younger than 19, living at home, and single status is defined as not living with a partner. Firm's trade *bho* is defined in section 2.3. The O*NET measure of Goldin (2014) is the average of the O*NET variables: Time Pressure, Contact with others, Structured versus Unstructured Work, Freedom to Make Decisions, Establishing and Maintaining Interpersonal Relationships. These variables characterize the typical related to an occupation. Their values are standardized on the full sample. Means of each O*NET characteristic across groups can be seen in Table A3.

and the time zone of the partner country:

$$bho_d = \max \left\{ 8 - \left| UTC_{DK}^d \text{ offset} \right|, 0 \right\} \quad (1)$$

where UTC is the coordinated universal time. We then construct an average *bho* measure for firm *j* by weighting by the number of 6-digit HS products from each partner country (both exports and imports) in the following way:

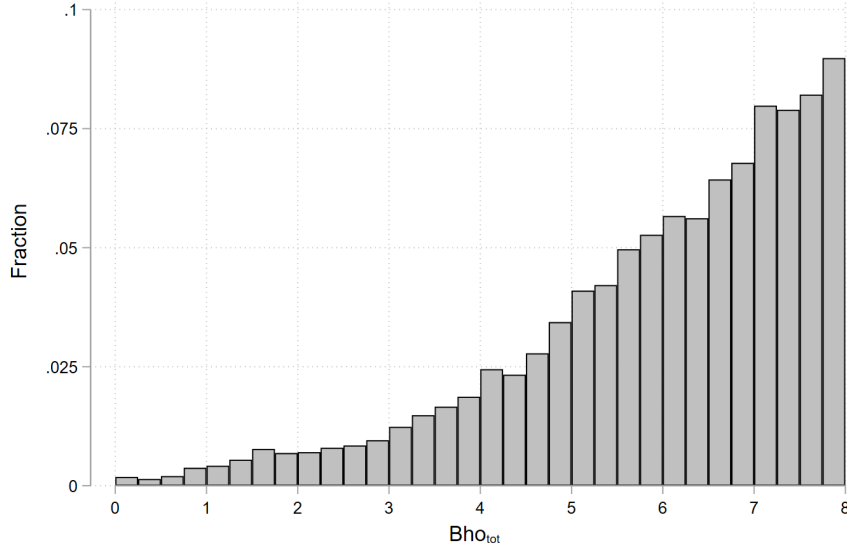

$$bho_{jt}^{\text{trade}} = \sum_{d \in D_{jt}} \frac{\text{Products}_{djt}^{\text{exp}} + \text{Products}_{djt}^{\text{imp}}}{\sum_{d \in D_{jt}} \text{Products}_{djt}^{\text{exp}} + \text{Products}_{djt}^{\text{imp}}} \cdot bho_d \quad (2)$$

where $\text{Products}_{djt}^{\text{exp}}$ is the number of exported products of firm *j* to country *d* in year *t*, and $\text{Products}_{djt}^{\text{imp}}$ is the number of imported products of firm *j* to country *d* in year *t*. D_{jt} is the set of countries firm *j* traded with in year *t*.

Figure 1 shows the distribution of *bho* for the firms in the sample. It is evident that many firms have close to complete business hour overlap with their trade partners, reflecting that partner firms are located in the same time zone as Denmark. However, a sizable portion of firms have a low *bho* which would tend to put pressure on local employees to work outside normal

business hours. In the empirical section we take logs of bho , which to 0.02% of the sample observations being dropped.

Figure 1: Distribution of bho , 2008-2017

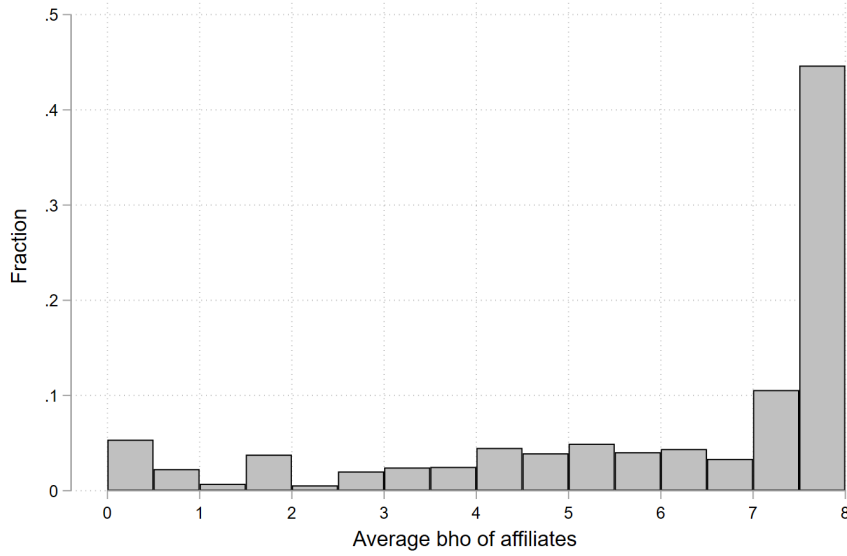

Note: This figure shows the distribution of average bho weighted by the variety of products imported and exported, for Danish international manufacturing firms, with more than 10 employees in 2008-2017.

We also construct a bho measure based on outward foreign direct investments by Danish firms by utilizing the FATO register. We define this bho measure by calculating a simple average of the business hours overlap of each firm's foreign affiliates, accounting for the number of foreign affiliates, $Affiliates_{djt}$, in each destination d :

$$bho_{jt}^{Affiliates} = \sum_{d \in D_{jt}} \frac{Affiliates_{djt}}{\sum_{d \in D_{jt}} Affiliates_{djt}} \cdot bho_d \quad (3)$$

Figure 2 shows the distribution of the bho measure based on foreign affiliates, and it is clear that this measure is more skewed towards full overlap in business hours than the trade based bho measure. Figures A2 in Appendix A show the evolution of the two bho variables over time.

Figure 2: Distribution of *bho* for foreign affiliates, 2010-2017

Note: This figure shows the distribution of average *bho* weighted by number of foreign affiliates in each country, for Danish international manufacturing firms, with more than 10 employees in 2010-2017, with at least 1 affiliate.

2.4 Gender gap index

Attitudes towards women may differ across destination countries. For robustness, following Bøler et al. (2018) we control for such differences by employing a Gender Gap Index from the World Economic Forum. It pertains to 2007 and covers 128 countries. The index measures relative gaps between men's and women's outcomes. These outcomes are "related to basic rights such as health, education, economic participation or political empowerment" (Hausmann et al., 2007, p. 3).⁸ For each firm, the index is an average weighted by product-destination country combinations, similar to the business hour overlap.

2.5 O*NET data

We also explore job characteristics that are likely to be associated with working across time zones. Following Goldin (2014), we add O*NET data by merging via ISCO occupation codes and focus on five occupational characteristics that in her judgement limit temporal flexibility of workers as they are linked to working particular hours and long hours. The five characteristics are: 1) Time pressure, 2) Contact with others, 3) Establishing and maintaining interpersonal relationships, 4)

⁸The dataset can be obtained at the World Bank website: <https://tcdata360.worldbank.org/indicators/af52ebe9?indicator=27959>, and more information about its construction can be found in the World Economic Forum's Gender Gap report, Hausmann et al. (2007).

Structured versus unstructured work, 5) Freedom to make decisions. See appendix B for more detailed information about the underlying questions in O*NET.

3 Empirical approach

Our estimation equation takes the following form:

$$y_{ijt} = \tau Female_i \cdot \ln bho_{jt}^{trade} + X'_{it}\beta + \delta_t Female_i + \rho_{ij} + \eta_{jt} + \epsilon_{ijt} \quad (4)$$

where the dependent variable is an indicator for whether worker i employed at firm j purchased prescription antidepressant medication in year t . The explanatory variable of interest is an interaction term between a female indicator for worker i and firm j 's business hour overlap with its trade partners in year t . Controls include: experience and its square, an indicator for having children, indicators for education, and occupational fixed effects. Most importantly, this specification controls for worker-firm (spell) and firm-year fixed effects. Finally, it controls for female-year fixed effects. Standard errors are clustered at the firm level.

Our identification strategy rests on three pillars. First, we condition on job-spell fixed effects, which means that we exploit variation over time in the firm's business hour overlap within a given worker-firm relationship. This allows us to account for idiosyncratic and time-invariant factors that affect individuals' health, such as pre-natal and early-life environment and genetic differences.

Second, we focus on the differential prevalence of antidepressant use between women and men. The underlying hypothesis is working across time zones is particularly difficult for women because of the need to juggle work and family obligations, and even more so for young women who are likely to have young children. This is in line with the findings of Bøler et al. (2018) who show that working across time zones is associated with a higher gender wage gap for this subpopulation. Focusing on the gender gap allows us to control for unobservable firm-year-specific heterogeneity such as corporate culture, average level of stress among the workforce, etc. In other words, we examine how the differential propensity to take antidepressants of men and women *working for the same firm in the same year* is related to the business hour overlap. The inclusion of firm-year fixed effects controls for factors driving firms' internationalization, and thus eliminates

the possibility that firms with healthier populations are more or less likely to internationalize. The inclusion of female-year fixed effects takes into account any differential propensity to use antidepressants between genders and its evolution over time.

Third, in addition to focusing on differences between men and women, we exploit differences between occupations. In particular, we conjecture that occupations with limited temporal flexibility, those necessitating greater interactions with others and those requiring establishing and maintaining personal relationships would be to a larger extent affected by a lower business hours overlap.

To reiterate, we hold the worker-firm match fixed, control for unobservable firm-year heterogeneity, and ask how a change in the firms' business hour overlap with its foreign buyers and suppliers translates into a differential antidepressant use among (i) its female and male workers, (ii) workers in occupations with limited temporal flexibility and occupations requiring greater interactions with others, establishing and maintaining personal relationships versus occupations where these factors play a lesser role.

4 Estimation results: Gender gap in mental well-being

4.1 Hypotheses

To reiterate, our hypothesis is that working across time zones requires work outside of standard business hours and disturbs the work-life balance. In turn, this may cause stress, lead to depression, and hence the use of anti-depression medication. However, not all employees are equally exposed to this risk.

Employees with the greatest exposure to this channel are those who directly communicate with business partners abroad. This includes: managers, sales representatives, marketing specialists, logistics and accounting staff, technical product support, supply chain managers, and others. Production workers are unlikely to be affected. Typically, workers in the former group will have a college education. Thus, we posit that the anticipated effects are likely to be seen among employees with college education.⁹

Further, we expect that the need for temporal flexibility is harder to achieve for women

⁹This is in line with the findings on business hours overlap and the gender wage gap in the study by Bøler et al. (2018).

(in line with arguments presented by Goldin (2014)), hence our focus on the gender gap in antidepressant usage. Finally, we expect larger effects among younger workers (due to general childcare responsibilities) and in particular among younger college-educated workers.

4.2 Baseline results

The hypotheses outlined above suggest that the largest effects should be found among younger college-educated workers. However, in the interest of transparency, we start by reporting the estimation results for the full sample. We also gradually add various fixed effects to shed light on how much (if at all) they matter. The results for the full sample, reported in the top panel of Table 2, show no statistically significant relationship between the business hour overlap and antidepressant usage. This is regardless of the set of fixed effects included in a given specification.

The next panel shows the results for the subpopulation of college-educated workers. Here, the anticipated relationship is statistically significant at the 10 percent level in all but two specifications (column 1-2). This pattern suggests the importance of including job spell and firm-year fixed effects. Spell fixed effects capture endogenous mobility and time-invariant characteristics of the worker. Firm-year fixed effects capture differences in the level of stress across sectors, firms of different types, firms with different workforce composition as well as within firms across time. Once spell and firm-year fixed effects are included, the inclusion of additional fixed effects hardly changes the magnitude or the significance level.

The magnitude of the estimated effects is economically meaningful. A decline in the business overlap by 5 hours, equivalent to moving all trade from Germany to the eastern part of Canada, is associated with a one-percentage-point increase in the likelihood of antidepressant use by women relative to men. This effect is sizeable, given the prevalence of antidepressant use in this subpopulation of 3.4%.

The next panel presents the estimation results for the subsample of workers under 45 years of age. The coefficients of interest are statistically significant at the one percent level in columns 3-6, but not in the first two columns, which excludes spell and firm-year fixed effects. The size of the estimated coefficients increases slightly and becomes significant at the 5 percent level, suggesting a 1.2 percentage point increase in the antidepressant gender gap as a result of a five-hour decline in business hour overlap. This is equivalent to a third of the average use for

this subgroup.

The bottom panel shows the estimates for the final subsample of young (under 45) workers with a college education. The estimated coefficients are larger than before. In our thought

experiment, they imply a 1.7 percentage point increase in the gender gap, which is more than half of the average for this group.

Taken together, our results are consistent with working across time zones causing stress and mental distress, particularly among women, and manifesting itself in a higher gender gap in the use of antidepressant medication.

4.3 Zooming in on single parents

One potential concern is that women may be more likely to seek medical treatment, including for mental health related conditions. To give us confidence that our results are indeed related to work across time zones putting a greater strain on work-life balance we ask whether a group that would be expected *a priori* to find balancing work and family obligations more challenging is affected by working across times zones to a greater extent. Namely, we focus on single mothers.

A substantial share of the Danish population chooses not to formalize their relationships through marriage. Therefore, we define a single parent as an adult living together with their own child under the age of 18, but not living with a non-related adult with a less than 15-year age difference from themselves. As one would expect, single parents constitute a relatively small share of the sample: 7.85% of college educated women and 9.27% of women without college education in the sample are single mothers. The corresponding figures for single fathers are 1.95% and 2.77%, respectively.

We estimate an extended specification, which allows for a differential effect of business hour overlap on single parents of either gender and cohabitating parents of either gender relative to employees without children. The results, presented in Table 3, focus on younger workers with and without college education (see columns 1 and 2 versus 3 and 4, respectively).

The result are in line with our priors. We confirm our baseline results as the interaction term *female * bho* remains negative and statistically significant in all specification and its magnitude is very similar to that found earlier. More importantly, the relationship between working across time zones and the use of antidepressants appears to be particularly strong for single mothers. The coefficient on the interaction terms *female * single parent * bho* is negative and 3-4 times larger in magnitude than the coefficient on the *female * bho* interaction. It is statistically significant at the one percent level in the subsample of college educated workers and at the five

percent level in the sample without college education. As anticipated, a lower business hours overlap is associated with a much higher antidepressant usage among college educated single mothers than among those without college education, echoing our earlier results.

FE on Spell, Firm-year, Female-year, and Education. Further controls are experience and experience squared. Occupational FE are based on 2-digit ISCO-code. Educational FE have 12 levels. The sample includes workers aged 20-44, in international manufacturing firms with more than 10 employees, in the years are 2008-2017. Parental status is defined by having a child younger than 19, living at home, and single status is defined by not living with a partner. Standard errors, clustered by firm, in parenthesis. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$.

Moving on to other estimates, we find that single mothers are more likely to use antidepressants, which is consistent with the findings from Finland showing that single mothers substantially increase their antidepressant use at the time of separation with only a moderate decline after

separation (Kühn et al., 2023). The opposite is true of college-educated single fathers, for whom business hours overlap also has the opposite sign. This is in line with the observation that men are less likely to see medical help, particularly if they are not in a relationship. Interactions terms with parent indicator variables do not appear to be statistically significant.

In summary, our finding of the impact of working across time zones on antidepressant usage being 3-4 times larger for single mothers than for women in general suggests that the pressures of maintaining work-life balance are likely to be one of the factors driving our results. The finding that the effect on single mothers is more than twice as large in the subsample of college educated workers than among those without college education is also consistent with our priors that skilled workers are more likely to hold positions requiring contacts with business partners abroad and thus are more likely to be affected the pressures of working across time zones. Finally, our confidence in the findings is further boosted by the fact they can confirm the results from another Nordic country on separation increasing antidepressant use among single mothers.¹⁰

5 Robustness checks

We subject our findings to several robustness checks. To save space we only present the results for the most stringent specification (described in equation 4) and for the subsamples of younger workers and younger workers with college education. These are the subsamples where the baseline exercise produced the largest effects.

5.1 Are our findings driven by gender attitudes in partner countries?

Another potential concern is that the business hour overlap may be correlated with societal attitudes, such as the position of women in the society in the partner countries, rather than just purely reflecting the time zone differential. For instance, it may be more difficult, less pleasant, and more stressful for female employees of Danish companies to conduct business in countries where women’s rights are restricted or women have a lower social status. Countries, where this is typically known to be the case, tend to be far away from Denmark and will thus have a low business hour overlap. If so, our findings could simply be reflecting the mental toll doing business under such conditions has on female employees, rather than the need for working outside the

¹⁰Recall that inclusion spell effects means that our results are identified of changes over time.

standard office hours due to time zone differences.

To address this concern, we control for attitudes towards women and gender equality in the trading partner countries. We follow Bøler et al. (2018) and use the Gender Gap Index which is compiled by the World Economic Forum and pertains to the year 2007 (see Section 2.4 for more information about the index). The value of the index relevant to each firm is calculated in a way analogous to the business hour overlap.

Columns 1 and 2 in Table 4 present specifications controlling for the Gender Gap Index. Our results are robust to the additional control and remain significant at one and five percent level in columns 1 and 2, respectively. The size of the estimated coefficients goes up, now implying a 2 percentage point effect resulting from a five-hour decline in business hour overlap. As for the effect of gender attitudes in partner countries, it is in the opposite direction of what one would expect, and significant for the first sample. Additional robustness checks (not reported here) show that if the time-varying GGI is used (instead of its 2007 value), its interaction with the female dummy becomes insignificant, while the effect of *bho* remains robust.

5.2 Are the results robust to excluding the Global Financial Crisis?

Our data include 2008 and 2009, which were the years of the Global Financial Crisis. To make sure that our results are not affected by the Global Financial Crisis, we re-estimated our baseline specification excluding observations for 2008 and 2009. The results, shown in columns 3 and 4 of Table 4, remain robust for college-educated workers.

5.3 Are similar effects found in Danish multinationals?

The logic of our exercise would imply that similar effects should be found in Danish firms with subsidiaries abroad. This is the question to which we turn next. As we include in the sample firms that do not engage in FDI, we control for whether or not a given firm has at least one foreign subsidiary in a given year and interact this variable with a female dummy. This allows us to distinguish the gendered effect of being a multinational firm from the effect of changing the *bho* with the subsidiaries. In other words, we capture both the extensive as well as the intensive margin.

The results, presented in columns 5 and 6 of Table 4, are in line with our hypothesis.

As expected, we find that a lower business hour overlap with foreign subsidiaries of Danish multinationals is associated with an increase in the relative use of antidepressants by women in the subsample of college-educated workers. Our main results for the business hour overlap based on firms' international trade flows remain robust for college educated workers. The coefficients are very similar to those found earlier, though the significance level is lower. The size of the coefficient on the trade-based business hour overall is more than twice as large as the size of the coefficient based on the *bho* with foreign subsidiaries. Finally, the estimates also suggest that the gender gap in antidepressant usage tends to be lower in multinational firms in general.

GGI trade is World Economic Forum's Gender Gap Index in the year 2007, weighted by the firm's trade variety. Bho foreign affiliates is average bho for a firm weighted by the number of foreign affiliates in each country. Further controls are experience, experience squared and having children. Occupational FE are based on 2-digit ISCO-code. Educational FE have 12 levels. The sample includes workers aged 20-44, in international manufacturing firms with more than 10 employees. Std. errors, clustered by firm in parenthesis. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$.

5.4 Worker exits

One may be concerned about the possibility that changes to business hours overlap induce some workers to leave the firm where they are employed, biasing our estimates. The direction of bias is not *a priori* clear. On the one hand, workers more prone to mental distress may be more likely to leave. On the other hand, they may be more likely to stay as they may find it more difficult to find alternative employment.

To shed some light on this issue, we examine worker exits from the firm. We observe some workers going to another employer, while others exit our sample. Recall that our dataset encompasses manufacturing firms with more than 10 employees engaged in imports and exports, hence the latter option may mean unemployment or employment in a firm outside our sample. We consider three possibilities: (i) exits from the firm regardless of whether or not we observe the worker in the sample afterwards, (ii) switching to another firm, or (iii) exit from the sample.

We focus on the differential impact of business hour overlap for exits by female workers. We control for a plethora of fixed effects described earlier. We consider the full sample, the subsample of college educated workers, the subsample of workers under 45 years of age, and the subsample of workers under 45 with college education. As evident from Appendix Table C2, the coefficient of interest never reaches conventional significance levels, regardless of the subsample and the definition of exit considered. This attenuates our concern about differential exit rates biasing our results.

6 Exploiting difference between occupational characteristics

Not all occupations require interactions with foreign business partners and thus working across time zones. For instance, such interactions are crucial for an account manager in charge of important customers abroad, but not for a production worker. In this subsection, we use variation in occupational characteristics to test our hypothesis that working across time zones is taxing for mental well-being.

Following Goldin (2014), we use O*NET data and focus on five occupational characteristics that in her judgment limit the temporal flexibility of workers, as they are linked to working particular hours and long hours. These are: time pressure, contact with others, establishing and maintaining interpersonal relationships, structured versus unstructured work (which captures

how easy it is to find a substitute for a given worker), and freedom to make decisions. We use the average of the characteristics for each 4-digit occupational code or an indicator variable for the top 25% of occupations ranked highest in terms of these characteristics. See section 2.5 and appendix B for more details.

Focusing on occupational characteristics is thus an alternative identification strategy that allows us to link working across time zones to mental well-being. We consider occupational variation in isolation, together with the gender effect as well as allowing for an interaction between the two. We estimate the following specification, which is an augmented version of equation 4:

$$\begin{aligned} \ln y_{ijt} = & \tau_1 ONET_i \cdot \ln bho_{jt}^{\text{trade}} + \tau_2 Female_i \cdot \ln bho_{jt}^{\text{trade}} \\ & + \tau_3 ONET_i \cdot Female_i \cdot \ln bho_{jt}^{\text{trade}} + X'_{it}\beta + \delta_t Female_i + \rho_{ij} + \eta_{jt} + \epsilon_{ijt} \quad (5) \end{aligned}$$

For the purpose of this exercise, each worker is assigned to their first occupation reported in the data set. This is done for two reasons. First, Kambourov and Manovskii (2009) suggests that the first-reported occupation code in a job spell tends to be more accurate. Second, we want to avoid possible endogeneity of mental well-being either driving workers to change occupations or preventing them from doing so. Note, that using time-invariant occupation codes means there is no need to include Female x ONET interaction, as it will be time-invariant and hence subsumed by the spell fixed effect.

We restrict our attention to workers under 45 years of age with a college education, which was the group that was affected the most, according to our earlier analysis. This is the group for whom the tension between professional and family obligations is likely to be the greatest.

We start by focusing on the measure encompassing all characteristics before considering them one by one. The results, presented in Table 5, support our hypothesis. We find a higher response of antidepressant usage to business hours overlap among employees in occupations that would be *a priori* expected to be more affected than among other workers. Both the continuous measure as well as the indicator variable for highly exposed occupations are negative and statistically significant when interacted with the business hour overlap. The estimated effect is economically meaningful: a decline in the business hour overlap from 8 to 3 hours is associated with a 0.9

percentage point increase in the antidepressant usage among workers in the highly exposed occupations (column 2). This is large, given the sample average of 3 percent.

Moreover, controlling for the impact of business hour overlap on occupations with particular characteristics does not affect our baseline findings that working across time zones leads to a greater gender gap in antidepressant usage. The interaction of interest maintains its sign and magnitude and remains statistically significant. This suggests that our baseline findings are not driven by self-selection of women into occupations that may have been more sensitive to working across time zones. This is also true if we allow the identified occupation to vary within a job spell, as can be seen in Appendix Table C1. Finally, the triple interactions are not statistically significant, which suggest that there is no interplay between the two effects.

In Table 6, we consider each of five occupational characteristics one by one. Not surprisingly, we find that business hours overlap differentially affects workers in occupations requiring

Table 5: Antidepressant use and job characteristics, college workers younger than 45

O*NET variable is Avg. of Time Pressure, Contact with others, Structured versus Unstructured Work, Freedom to Make Decisions, Establishing and Maintaining Interpersonal Relationships. Further controls are experience, experience squared and having children. Educational FE are based on 12 categories. The sample includes workers aged 20-44 with a college degree in international manufacturing firms with more than 10 employees. D() denotes a dummy for the variable being above the 75th percentile. The first occupation in the job-spell is used for determining the O*NET characteristic. The years included are 2008-2017. Std. errors, clustered by firm in parenthesis. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$.

establishing and maintaining personal relationships, occupations where contact with others is important, and occupations with few close substitutes. Differences in occupations along the time pressure dimension or freedom to make decisions are not statistically significant. As before, our findings on women being affected more than men by the need to work across time zones remain robust.

In summary, two different identification strategies, one based on gender differences and one on occupational characteristics, point in the same direction. This gives us confidence in our finding that working across time zones takes a toll on mental well-being of workers.

7 Conclusions

This paper documents some underappreciated consequences of globalisation on mental well-being. It argues that trading with business partners located in different time zones puts a greater burden on workers by necessitating working outside the standard business hours.

We use matched employer-employee data from Denmark, combined with information on workers' use of prescription antidepressant medication and transaction-level information on firms' import and export activities. Our identification strategy rests on several pillars. First, we condition on job-spell fixed effects in our estimation, i.e., the source of our variation is the change over time in the firm's business hour overlap within a given worker-firm relationship. Second, we focus on the gap in antidepressant usage between women and men working for the same firm in a given year, which allows us to control for unobservable firm-year-specific heterogeneity that may drive firms' internationalization, corporate culture, the average level of stress among the work-force, etc. We focus on the gender differential as working across time zones may be particularly taxing for the mental well-being of women for whom non-standard working hours clash with family obligations. Finally, we exploit differential effects associated with occupational characteristics, such as the need to establish and maintain interpersonal relationships or contact with others.

Our findings indicate that a decline in the business hour overlap between a Danish firm and its foreign business partners is associated with an increased incidence of antidepressant use among women relative to men. A decline in business overlap by 5 hours, equivalent to moving all trade from Germany to the eastern part of Canada, leads to a 1.7% point increase in the likelihood of antidepressant use by women relative to men among college-educated workers under 45. This implies increasing the prevalence of antidepressant use by 57%, which in this subpopulation is equal to 3%. Our analysis further shows that the impact of working across time zones on antidepressant usage is more three times larger for single mothers than for women in general, which suggests that the pressures of maintaining work-life balance are likely to be one of the key factors driving our findings. Finally, we show that *in addition* to the gender effect, workers in occupations where contact with others or establishing interpersonal relationships is important are affected to a greater extent.

Goldin (2014) convincingly argued that enhancing the temporal flexibility of jobs is what is needed to achieve greater convergence in labor market outcomes of men and women. Our results suggest that globalisation may make this task more challenging.

Appendices

A Descriptive statistics

A.1 Base descriptive

Table A1: Proportion of overall Danish economic activity covered by our sample after restrictions

	Employment	Sales	Imports	Exports
Manufacturing	12.1%	21.2%	31.0%	59.5%
10 employees	11.1%	20.3%	30.4%	58.9%
Share of manufacturing	92.0%	95.5%	98.0%	98.9%
Imports and exports	9.9%	19.0%	30.1%	58.5%
Share of manufacturing	81.4%	89.4%	96.8%	98.2%

The sample conditions are cumulative, such that the 10 employees condition also includes the manufacturing condition, and the imports and exports condition, includes both of the above. The employee condition has been implemented such that if a firm in a single year has fewer employees, but more than 10 in the year before and the year after, it is kept in the sample for that year.

Table A2: Means for workers with any AD usage 2008-2017

	Men		Women	
	College	No college	College	No college
Years in sample	5.858	5.447	5.702	5.293
Years of AD use	2.631	2.300	2.581	2.372
Consecutive years in sample after first year	4.133	3.716	4.060	3.715
Distinct spells in sample after first year	1.141	1.161	1.105	1.114
Consecutive years of AD use after first year	2.476	2.151	2.436	2.235
Distinct spells of AD use after first year	1.155	1.149	1.145	1.137
Unique persons	4,138	18,666	3,730	11,081

The sample includes workers aged 20-60, in international manufacturing firms with more than 10 employees, that have bought prescription antidepressants at any point in 2008-2017. The years included are 2008-2017.

Table A3: Means of O*NET characteristics for workers in 2008-2017

	Men		Women	
	College	No college	College	No college
Goldin (2014) O*NET measure	0.530	−0.256	0.583	−0.147
Time Pressure	−0.442	0.210	−0.290	0.023
Contact With Others	0.337	−0.222	0.499	−0.016
Structured versus Unstructured Work	0.659	−0.292	0.588	−0.174
Freedom to Make Decisions	0.618	−0.221	0.532	−0.285
Establishing and Maintaining Interpersonal Relationships	0.670	−0.366	0.697	−0.059
Observations	356,405	1,005,479	220,488	404,694

The sample includes workers aged 20-60, in international manufacturing firms, with more than 10 employees. The years included are 2008-2017. The O*NET measure of Goldin (2014) is the average of the O*NET variables: Time Pressure, Contact with others, Structured versus Unstructured Work, Freedom to Make Decisions, Establishing and Maintaining Interpersonal Relationships. These variables characterize the typical related to an occupation. Their values are standardized on the full sample.

Figure A1: Proportion of AD users in subgroups of the population, 2008-2017

Note: This figure shows the evolution in the shares of workers aged 20-60, in international manufacturing firms, that have bought reception antidepressants in a given year.

Figure A2: Average *bho*, 2008-2017

Note: This figure shows firms' average trade business hour overlap weighted by both exports and imports, and for firms engaged in FDI, their average business hour overlap weighted by the number of foreign affiliates in 2010-2017. The average is weighted by persons in the sample, which are workers aged 20-60, in international manufacturing firms.

A.2 Variation in AD usage and *bho* at the firm level

Figure A3: Distribution of within-firm, yearly, log changes in trade *bho*, 2008-2017

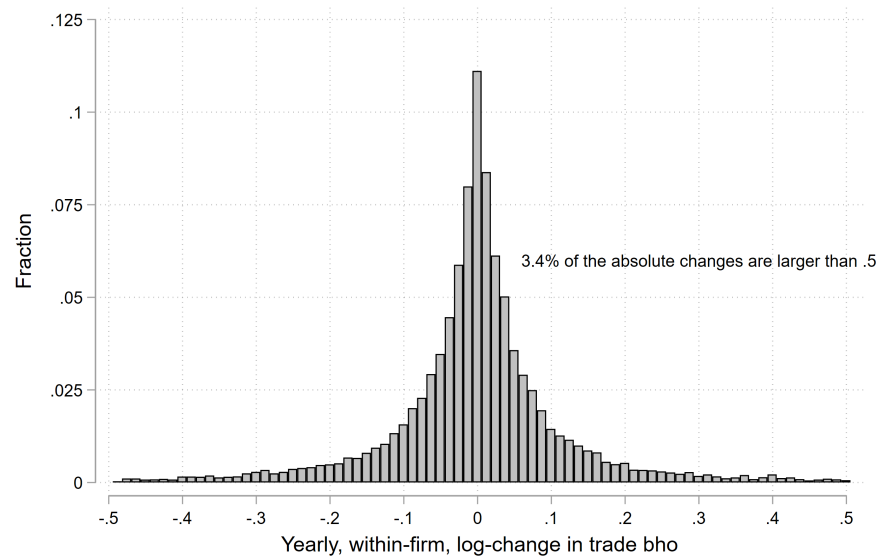

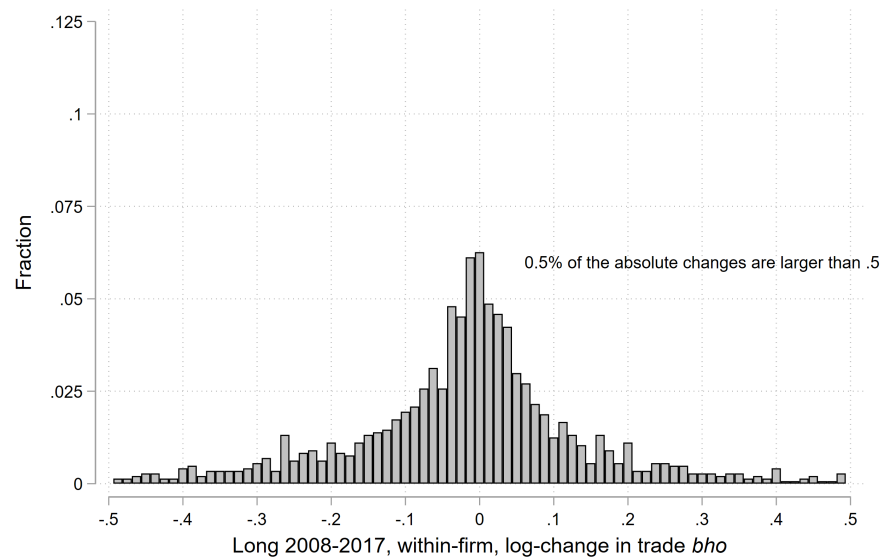

Figure A4: Distribution of within-firm, long 2008 to 2017, log changes in trade *bho*

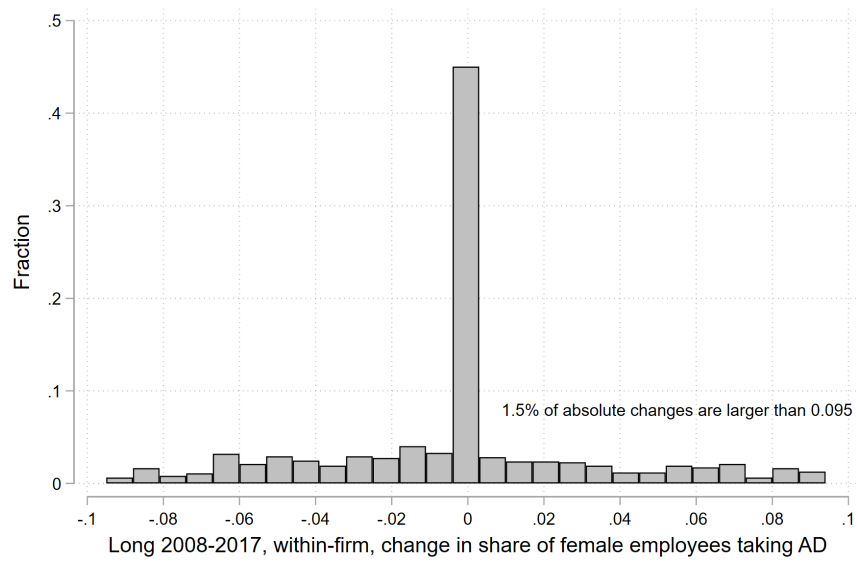

Note: Only firms present in both 2008 and 2017 are included

Table A4: Statistics on the absolute value of within-firm yearly log changes in *bho*

	Affiliate <i>bho</i>	Trade <i>bho</i>
%-Share equal to zero	79.20	1.81
80th percentile	0.00	0.14
90th percentile	0.07	0.26
95th percentile	0.18	0.43
99th percentile	0.69	1.02

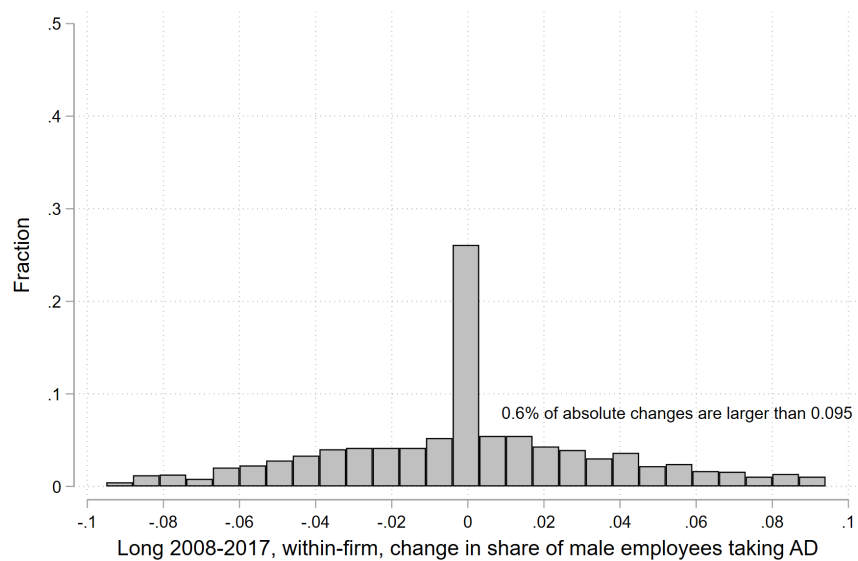

The changes for affiliate *bho*, only include the internal margin, so changes for firms that have foreign affiliates

Figure A5: Distribution of long 2008 to 2017, within-firm, change in share of female workers taking AD

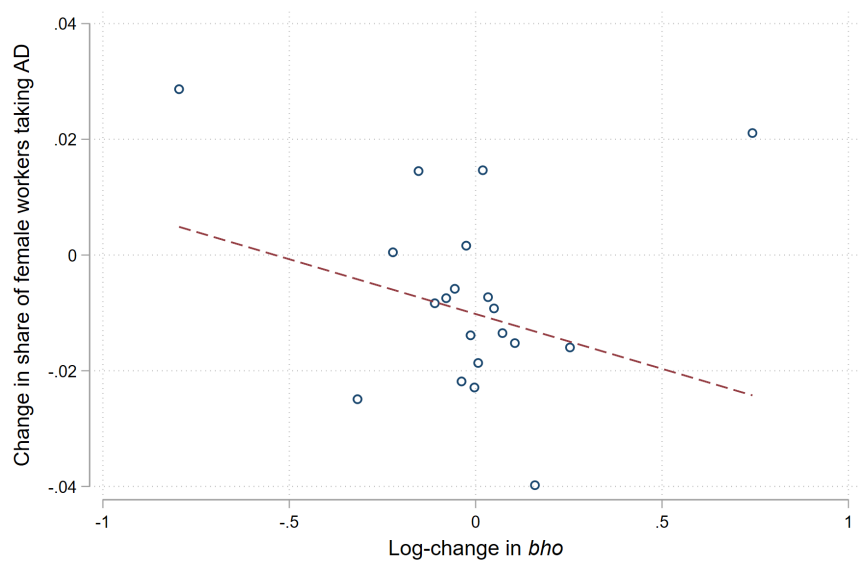

Note: Only firms with female workers in both 2008 and 2017 are included

Figure A6: Distribution of long 2008 to 2017, within-firm, change in share of male workers taking AD

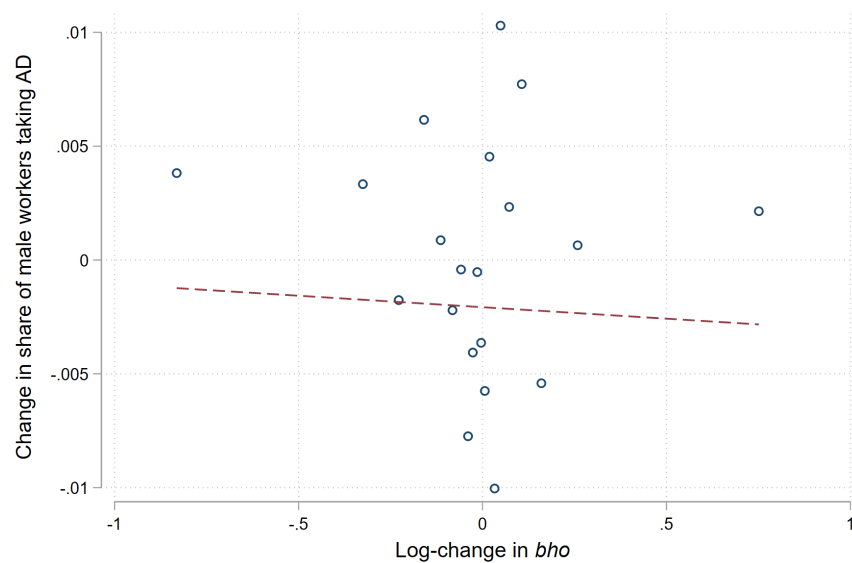

Note: Only firms with male workers in both 2008 and 2017 are included

Figure A7: Binned scatter plot of long 2008 to 2017, within-firm, change in share of female workers taking AD and log *bho*

Note: Only firms with female workers in both 2008 and 2017 are included. The fitted line is a regression line.

Figure A8: Binned scatter plot of long 2008 to 2017, within-firm, change in share of male workers taking AD and log *bho*

Note: Only firms with male workers in both 2008 and 2017 are included. The fitted line is a regression line.

B O*NET survey

Below we reproduce the questions used in the O*NET survey and Goldin's interpretation (see notes to Table 2 in Goldin (2014)). These are:

- Time pressure: *How often does this job require the worker to meet strict deadlines?* Lower pressure means worker does not have to be around at particular times.
- Contact with others: *How much does this job require the worker to be in contact with others (face-to-face, by telephone, or otherwise) in order to perform it?* Less contact means greater flexibility.
- Establishing and maintaining interpersonal relationships: *Developing constructive and cooperative working relationships with others, and maintaining them over time.* The more working relationships, the more workers and clients the employee must be around.
- Structured versus unstructured work: *To what extent is this job structured for the worker, rather than allowing the worker to determine tasks, priorities, and goals?* If the job is highly structured to the worker, there would be a lower chance that the worker would have close substitutes.
- Freedom to make decisions: *How much decision-making freedom, without supervision, does the job offer.* Generally means that the worker determines what each client should receive, rather than being given a specific project, and thus workers are poorer substitutes for each other the greater are these freedoms.

C Robustness checks

Table C1: AD, ONET characteristics with within job spell varying occupations

	(1)	(2)	(3)	(4)	(5)	(6)
Female \times ln(bho trade)			-0.0168** (0.008)	-0.0168** (0.008)	-0.0144* (0.007)	-0.0155** (0.008)
ln(bho) \times O*NET	-0.0007 (0.000)		0.0004 (0.001)		0.0005 (0.001)	
ln(bho) \times D(O*NET)		-0.0014* (0.001)		-0.0000 (0.001)		0.0000 (0.001)
Female \times O*NET			-0.0045** (0.002)		0.0021 (0.008)	
Female \times D(O*NET)				-0.0056* (0.003)		-0.0012 (0.016)
Female \times ln(bho) \times O*NET					-0.0041 (0.005)	
Female \times ln(bho) \times D(O*NET)						-0.0026 (0.009)

Average AD usage	0.0303	0.0303	0.0303	0.0303	0.0303	0.0303

O*NET variable is Avg. of Time Pressure, Contact with others, Structured versus Unstructured Work, Freedom to Make Decisions, Establishing and Maintaining Interpersonal Relationships. Further controls are experience, experience squared and having children. Educational FE are based on 12 categories. The sample includes workers ages 20-44 with a college degree in international manufacturing firms with more than 10 employees. D() denotes a dummy for the variable being above the 75th percentile. The years included are 2008-2017. Std. errors, clustered by firm in parenthesis. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$.

Table C2: Effect of business hour overlap on exit

	(1) Exit sample	(2) Exit firm	(3) Switch firm
Panel A: All workers			
Female \times ln(bho trade)	-0.0048 (0.007)	-0.0022 (0.008)	0.0026 (0.004)

Exit sample means leaving the dataset either through unemployment or switching to a firm not included in the sample. Exit firm means exiting the firm either by leaving the sample or switching to another firm in our sample. Further controls are experience, experience squared and having children. Occupational FE are based on 2-digit ISCO-code. Educational FE have 12 levels. The sample includes workers aged 20-60, in international manufacturing firms with more than 10 employees, in the years are 2008-2016. Standard errors, clustered by firm, in parenthesis. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$.
